GENERAL FRAMEWORK

This is the second annual report dealing with natality and mortality patterns observed at the health unit level. This volume contains birth and death statistics and related indices for the year 1984 for Alberta and is disaggregated by 27 Health Units. The tables and figures which follow provide an overview of natality and mortality in this province from the perspective of individual health units at least to the extent that this is possible from vital statistics.

By considering births and deaths on a health unit basis, this report acknowledges the differences that exist from one area of the province to another. It is not always possible to offer an explanation as to why such variation exists, and no attempt has been made in this volume to provide one. Any explanation would need to be based on a comprehensive understanding of the various demographic and socio-economic characteristics of the health units and this knowledge is most readily available at the community level.

In data format this report closely resembles the second report published in July 1985(1). The emphasis is on natality and mortality of individual health units as observed in 1984. The point of view has been adopted that the situation for Alberta is mainly relevant insofar as it provides a convenient standard for gauging patterns in this province. To that end, all age-standardized rates in the report have been standardized to an Alberta population 1984. It is hoped this information will prove useful to those involved in planning at both the health unit and provincial levels.

Many of the notions considered in this report will be new to certain readers. So it is necessary to have an educational component to the report. As each new demographic indicator is introduced it is accompanied by the corresponding background material or mathematical formula. Appendix A gives the details of the demographic methods used. The report is divided into four chapters, dealing with births, stillbirth and infant mortality, deaths in the male popula-

1 Division Support Branch, Alberta Social Services and Community Health, Birth and Death Statistics by Local Health Authorities, 1983. Edmonton: Alberta Social Services and Community Health.

tion, and deaths in the female population, respectively. Before proceeding to a general discussion of the chapter contents, a few remarks are in order concerning the statistics upon which this report is based and produced.

BIRTH AND DEATH STATISTICS

All the birth and death statistics used in the preparation of this report originated with Alberta Vital Statistics. A proper interpretation of the tables and figures in the pages that follow requires an understanding of some of the features of the Alberta Vital Statistics registration and reporting system. As each birth or death is registered, Alberta Vital Statistics assigns the vital event to a health unit on the basis of the registrant's place of usual residence, provided, of course, that the individual involved is an Albertan. This may or may not be the health unit where the vital event took place.

Alberta Vital Statistics also registers births and deaths involving residents of other provinces and countries, but these will not be considered here. By the same token, if a resident of Alberta gives birth or dies while outside this province, the registration will not be known to Alberta Vital Statistics. This results in a small degree of undercounting with respect to vital events involving Albertans; however the shortfall is not large (approximately 448 births (1%) and 227 deaths (2%) in 1983.(2)

The single exception to the above method of reporting has to do with residents of certain Indian reservations. Because of a special arrangement between the neighbouring health units and Alberta Vital Statistics, births and deaths involving residents of these reservations are not assigned to the health unit in question, but rather given their own identifier.(3, 4) This makes it impossible to assign these vital events to a health unit without going back to the original registrations. Consequently these statistics have been excluded from the present report. However, data from

-
- 2 Statistics Canada, 1984. Vital Statistics: Volume 1, Birth and Deaths, 1983. Ottawa: Minister of Supply and Services Canada. Catalogue Number 84-204.
 - 3 Division Support Branch, Alberta Social Services and Community Health, 1983. A Study of the Methods of Reporting Vital Statistics and Communicable Diseases by Local Health Authority (unpublished document).
 - 4 Birth and Death Statistics by Local Health Authority - 1983, opcit.

Alberta Vital Statistics indicate that the resulting undercounting is small (approximately 70 births (0.15%) and 32 deaths (0.25%) in 1983).

Alberta Vital Statistics publishes an Annual Report containing, along with other information, birth and death statistics. In theory, the entries in the 1984 report should coincide exactly with those given here. However, certain discrepancies can be found. For example, Alberta Vital Statistics sets the total number of deaths (Alberta residents only) at 12,386 which is to be compared to 12,507 computed from Tables 2.3 and 3.3 in this report. Other differences can be found for births and for different causes of death. The explanation is that the Alberta Vital Statistics system is a dynamic one, with registrations being updated, late registrations being filed and similar data modifications made. Since this report was prepared over half a year after the 1984 annual report was assembled by Alberta Vital Statistics, it is to be expected that differences will exist. However, from the point of computing health indices these differences are not important. At the same time, this also means that the statistics used in the present report are actually going to be slightly more accurate and complete than those going into the Alberta Vital Statistics Annual Report.

POPULATION ESTIMATES

A large part of this report is concerned with birth and death rates. To compute these it is necessary to have estimates of population size. Certain of the health units are included in a municipal census, and in these cases up-to-date enumerations are available. In order to have a uniform method applicable to all health units it was decided to estimate all 1984 health unit populations by projecting the health unit enumerations from the national census of 1981. The details of the method of projection are given in Appendix A.

SMALL AREA STATISTICS

The preceding sections dealt with some of the characteristics of the statistics that have been used in this report. A related consideration has to do with the problem of small area statistics.(5, 6) This refers to the difficulties inherent in the analysis of statistics arising out of relatively sparsely populated areas. Because of the small numbers involved, indices computed from such statistics tend to be subject to random fluctuation. In the context of the present report, differences that appear to exist between one health unit and the next may be partly due to chance variation.

CHAPTER CONTENTS

Each chapter begins with a description of the relevant population according to age group, and follows with a series of tables and figures dealing with either births or deaths. The latter are organized according to a definite format which will become apparent as the contents of the chapters are described. Within each chapter, pages are numbered consecutively. Tables and figures will be identified by referring to the corresponding page number.

CHAPTER 1. LIVE BIRTHS

Table 1.1 gives population estimates for females in the reproductive years (10-49) by five-year age groups, computed using the method described in Appendix A. Note that in this table the far right column gives the total number of females in each health unit and that the bottom row gives the provincial total for each age group.

Table 1.2 is derived directly from Table 1.1, and gives the percent of the population in each health unit falling in each of the age groups in the range 10-49. Due to rounding the row totals may not sum to 100.

5 Ibid.
6 Diehr, R. 1984. Small area statistics: large statistical problems. American Journal of Public Health 70: 313-314.

Table 1.3 gives the number of live births by age group and health unit. Once again the totals for the health units and Alberta are provided.

Table 1.4 gives the age-specific live birth rates (per 1,000 females). These rates, sometimes called fertility rates, are defined by:

$$\frac{\text{number of live births to women in age group}}{\text{number of women in age group}} \times 1,000 .$$

Although not shown, it is possible to assign confidence intervals to each of the rates in this table along the lines of Table 1.5. The method of computation is described in Appendix B. Because of the small numbers involved in some of the health units, the age-specific rates in this table would be expected to have rather wide confidence intervals. For this reason Table 1.4 should be interpreted with caution, especially when health units are being compared.

Table 1.5 has a number of indices related to the age-standardized live birth rates for the year 1984. The technique of age-standardization is discussed in Appendix B. In the present case, rates have been standardized to the 1984 Alberta female population, ages 10-49. This means that each of the age-standardized rates appearing in the first column of the table (where they are referred to simply as rates) is the live birth rate that would have been observed in each health unit in 1984 if the age distribution of women in the reproductive years in the health unit had been precisely the same as that observed in Alberta as a whole in the year 1984. This adjustment for differing age distributions (see Table 1.2) corrects for a potential source of artifactual error.

Associated with each of the (age-standardized) rates is a 95% confidence interval, with lower and upper limits shown in columns two and three. For details of the method of computation see Appendix B. These numbers bound the observed rate from below and above, respectively, and thereby give a range of numbers which include the true underlying rate with 95% confidence. The observed rate is simply one manifestation of the true underlying rate, which cannot be known with 100% confidence because of random variation. This means that the true underlying rate could be as small as the lower bound or as large as the upper bound. Typically the larger the population in question the narrower will be the confidence interval. Because they measure the reliability of the observed rate, the lower and upper confidence limits should always be considered along with the rate.

In the fourth column the rates (excluding that for Alberta) have been ranked from 1 to 27, with 1 for the largest rate and 27 for the smallest.

The fifth column gives ratios, computed by dividing the rate for each health unit by the Alberta rate. This gives a measure of the relative magnitude of the rate for each health unit compared to Alberta as a whole. The ranks and ratios are simply different ways of looking at the rates in column one.

The final column records the results of statistically testing for a difference between the rate for each of the health units and the rate for Alberta. The principles involved are described in Appendix B. If the health unit rate was found to be larger than that for Alberta, and statistically significantly so, then a "Yes" was entered next to that health unit. If the health unit rate was observed to be less than the Alberta rate, or larger but not statistically significantly larger, then a dot was entered instead. Another approach to statistical testing would have involved looking for significant departures of the health unit rates from the Alberta rate whether higher or lower, and not just higher as in this report. However this would have meant using a test with less sensitivity to detect higher than average health unit rates. Since these are the departures which tend to be of most interest (especially in the case of death rates) the present approach was adopted.

It must be reiterated that statistical significance is purely a property of numbers; as a concept it has no biological, demographic or social content. Consequently, even if two rates are determined to be different in a formal statistical sense, it is another matter as to whether or not they are different in a biological (or other) sense. Since this is a judgement to be made by the informed reader - it is outside the realm of statistical tests.

Figure 1.6 is a map of the health units with the ranks from Table 1.5 inscribed. This provides a convenient method of searching for clusters of low or high ranks.

Tables 1.7 - 1.9 give the number of live births by order, where first order means the first live birth for the woman and similarly for higher order of births.

Tables 1.10 - 1.11 give a breakdown of live births by weight category.

Tables 1.12 - 1.14 and Figure 1.15 are similar in layout (and interpretation) to Tables 1.3 - 1.5 and Figure 1.6, except that here attention is restricted to live births to women who were single (that is, not legally married) at the time of birth.

Table 1.16 is computed directly from Table 1.12 and gives the percent of the live births occurring in each age group. Due to rounding errors row totals may not equal 100.

Table 1.17 - 1.18 and Figure 1.19 are, once again, formatted along the lines of Tables 1.3 - 1.5 and Figure 1.6, except that a single age group, the 15 - 19 year olds, is considered in detail. Consequently the age-specific and age-standardized rates coincide.

Table 1.20 - 1.21 and Figure 1.22 consider live births to single teenagers.

CHAPTER 2. STILLBIRTHS AND INFANT MORTALITY

This chapter presents a fairly detailed treatment of stillbirths and infant mortality in Alberta and the health units. First, data for stillbirths are provided. This is followed by infant mortality rates which also includes perinatal, early neonatal, late neonatal and post-neonatal mortality. The following figure illustrates the concept of stillbirths and infant mortality.

FIGURE A

Table 2.1 - 2.2 gives the number of stillbirths among married females by age group and health units. Once again, the totals for the health units and Alberta are provided. Similarly, Table 2.2 shows the number of stillbirths among single females.

Table 2.3 presents the stillbirth ratios (per 1,000 births) for the health units and Alberta. Stillbirth ratios are defined by:

$$\frac{\text{stillbirths}}{\text{live births}} \times 1,000 \quad .$$

It is the number of stillbirths relative to the number of livebirths. Since stillbirth statistics are less reliable than might be wished, stillbirth ratios should be interpreted with caution.

Table 2.4 shows the number of infant deaths and infant death rates, defined by:

$$\frac{\text{number of deaths under 1 Year of Age}}{\text{number of live births}} \times 1,000 \quad .$$

Table 2.5 gives the age distribution of infant deaths (early neonatal deaths, late neonatal deaths and post-neonatal deaths).

Table 2.6 gives the number of perinatal deaths and perinatal death rates (per 1,000 births). Perinatal deaths consist of stillbirths and deaths within the first week of life. The perinatal death rate is defined by:

$$\frac{\text{stillbirths and first week deaths}}{\text{stillbirths and live births}} \times 1,000 \quad .$$

Since stillbirths and first week deaths are approximately equal, and since stillbirth statistics are somewhat unreliable, as mentioned earlier perinatal death rates must be also interpreted with caution.

CHAPTERS 3 and 4. DEATHS

Chapters 3 and 4 deal with deaths in the male and female populations, respectively. The two chapters are identical in layout except that Chapter 3 includes prostate cancer and Chapter 4 includes female breast cancer. The usual approach to presenting mortality data by age group uses five-year age groups in the range from 5 to 85. For technical reasons it was not possible to fit this many columns on a page, and so somewhat broader age groups were used. These have been defined by aggregating five-year age groups in such a way as to cover meaningful periods in the lifespan. For example, 5 - 14 for the school years, 15 - 24 for early adulthood, etc.

The age-specific male death rate (per 100,000 males) is defined by:

$$\frac{\text{number of deaths to males in age group}}{\text{number of males in age group}} \times 1,000 \quad .$$

The female rate is defined similarly. The age-standardized death rates in Chapters 3 and 4 have been standardized to the male and female populations of Alberta in 1984, respectively. So for each health unit, the male (female) age-standardized death rate for a given cause equals the death rate that would have been observed in that health unit if it had had the age distribution of males (females) in Alberta as a whole in 1984.

The format for Chapters 3 and 4 is basically the same as that used in Chapter 1. Following a description of the population by age group there is a series of four page units, each dealing with a specific cause of death. Each unit is structured along the lines of Tables 1.3 - 1.5 and Figure 1.6 of Chapter 1. Because there are far fewer deaths than live births per year, and because the deaths are spread out over both sexes and all age groups, the tables in Chapters 3 and 4 are much sparser looking than those of Chapter 1. As a result, the confidence intervals for the age-standardized death rates are generally quite wide. To an even greater degree this remark applies to confidence intervals for age specific death rates (not shown). For this reason, death rates should be interpreted with considerable caution. When a confidence interval lower limit extended into the negative numbers it has been reported

as such; another approach would have been to arbitrarily set it equal to 0. In certain cases several health units were found to have identical (age-standardized) rates. When this happened, ranks for these health units were assigned randomly rather than giving each of the health units involved the same intermediate rank. For the most part ties were due to several health units having no deaths due to a cause, and hence a rate of 0. Note that death rates are given per 100,000 males or females, whereas live birth rates are per 1,000 females.

The causes of death selected for study have been listed in the accompanying table along with the rubrics according to the International Classification of Diseases - ninth revision (ICD-9). The causes have been ordered in the table and in the chapters in ascending order of rubric number, except for prostate cancer in Chapter 3 and female breast cancer which has been placed at the end of Chapter 4. Because of this arrangement the tables and figures in Chapters 3 and 4 correspond by page numbers.

LIST OF SELECTED CAUSES OF DEATH

Cause of Death	ICD-9 Rubrics
All Causes	1 - 999
All Cancer	140 - 208
Colon Cancer	153 - 154
Lung Cancer	162
Female Breast Cancer	174
Prostate Cancer	185
Diabetes Mellitus	250
Ischemic Heart Disease	410 - 414

BREAST CANCER, FEMALES, 1984

APPENDICES

APPENDIX A

In this appendix the method of health unit population projection used in the report is described. The statistics needed consist of: the 1981 health unit census enumerations, the 1981 Alberta enumeration, and the 1984 Alberta post-censal estimates. All of these statistics are available directly or indirectly (through Alberta Bureau of Statistics) from Statistics Canada.

The method of projection simply scales the 1981 population of each health unit, by age group and by sex, according to a factor which relates the 1981 population of Alberta to that of 1984.

For a given sex, let $n_{ij}(81)$ equal the number of individuals in the i^{th} age group of the j^{th} health unit in 1981, and let $N_i(81)$ equal the number of individuals in the i^{th} age group in Alberta as a whole in 1981. For Chapter 1 and 2 there are eight age groups, and for chapters 3 and 4 there are ten. The corresponding numbers for 1984 are $n_{ij}(84)$ and $N_i(84)$. The problem is to estimate $n_{ij}(84)$ from $n_{ij}(81)$, $N_i(81)$ and $N_i(84)$. Defined by:

$$f_i(81,84) = \frac{N_i(84)}{N_i(81)}$$

The $f_i(81,84)$ scales the 1981 Alberta population in the i^{th} age group to that of 1984 in the sense that $f_i(81,84) N_i(81) = N_i(84)$. The project estimate of $n_{ij}(84)$ is then defined by:

$$n_{ij}(84) = f_i(81,84) n_{ij}(81).$$

Note that the same factor $f_i(81,84)$ is used for the i^{th} age group for all health units and so the assumption has been made that there has been a uniform of growth (or decline) common to all health units.

APPENDIX B

In this section the standardization methods and statistical techniques used in the report are described. The discussion applies to both live birth rates and death rates. For concreteness the discussion will be phrased in terms of death rates.

As in Appendix A, let n_{ij} equal the number of individuals in the i^{th} age group of the j^{th} health unit (for a given sex and year) and let d_{ij} be the corresponding number of deaths (for a given cause). Summing n_{ij} and d_{ij} over the index j (that is, over all health units) results in the number of individuals and deaths in the i^{th} age group in Alberta as a whole, denoted by N_i and D_i , respectively. The total number of Albertans and the total number of deaths is obtained by summing N_i and D_i over the index i , and will be denoted by N and D , respectively.

The death rate for the i^{th} age group and j^{th} health unit is defined by:

$$r_{ij} = \frac{d_{ij}}{n_{ij}},$$

and the corresponding rate for Alberta defined by:

$$R_i = \frac{D_i}{N_i}.$$

The standard error of r_{ij} may be estimated(1) by:

$$SE(r_{ij}) = \frac{d_{ij}^{\frac{1}{2}}}{n_{ij}},$$

and a 95% confidence interval constructed from

$$r_{ij} \pm 1.96 SE(r_{ij}).$$

Formulas are similarly defined for R_i .

1 Chiang, C.L. 1984. The Life Table and Its Applications. Malabar: Krieger.

The age-standardized death rate for the j^{th} health unit, standardized to the Alberta population, is defined by:

$$\text{sdr}_j = \sum_i W_i r_{ij},$$

where

$$W_i = \frac{N_i}{N}$$

Consequently, sdr_j is a weighted average of age-specific death rates for the j^{th} health unit, where the weights W_i are determined by the Alberta age distribution.

The standard error of sdr_j is defined by:

$$\text{SE}(\text{sdr}_j) = \left(\sum_i [W_i \text{SE}(r_{ij})]^2 \right)^{\frac{1}{2}}.$$

Since age-standardization is according to the Alberta population, the age-standardized death rate for Alberta, given by:

$$\text{SDR} = \sum_i W_i R_i,$$

simplifies to

$$\text{SDR} = \frac{D}{N},$$

which is usually referred to as the crude death rate. From an earlier formula,

$$\text{SE}(\text{SDR}) = \frac{D^{\frac{1}{2}}}{N}.$$

A test of the hypothesis that the standardized rate for the j^{th} health unit differs from the Alberta rate may be based on the Z - statistic.

$$Z = \frac{\text{sdr}_j - \text{SDR}}{(\text{SE}(\text{sdr}_j)^2 + \text{SE}(\text{SDR})^2)^{\frac{1}{2}}}$$

For the (one-sided) hypothesis that sdr_j is greater than SDR, the test is significant (at the 5% level) if

$$Z \geq 1.64 .$$
